Who this CAAP applies to

This CAAP applies to holders of Air Operator Certificates (AOCs) for low capacity and high capacity Regular Public Transport (RPT) operations.

The Civil Aviation Safety Authority (CASA) recognises that the operations to which this CAAP will apply are numerous and varied, and will endeavour to adopt a flexible approach consistent with the maintenance of good standards. Low Capacity RPT operators should take this into account when reading this document and considering its implications for their style of operations.

This CAAP should be read in conjunction with CAAP SMS 1(0) Safety Management Systems for RPT Operations and CAAP SMS 2(0) HF Training and Non Technical Skills Assessment for RPT Operations.

Why this publication was written

This CAAP provides advice and guidance for integrating Human Factors (HF) into an RPT operator’s SMS. It is crucial that HF is integrated at every opportunity, and not considered separately.

Status of this CAAP

This is the first CAAP written on this subject.

For further information

For application and policy advice contact CASA’s Human Factor’s Manager (Telephone 131 757).
Accident: An occurrence associated with the operation of an aircraft which takes place between the time any person boards the aircraft with intention of flight until such time as all such persons have disembarked, in which:

- a person is fatally or seriously injured as a result of:
  - being in the aircraft, or
  - direct contact with any part of the aircraft, including parts which have become detached from the aircraft, or
  - direct exposure to jet blast,
  except when the injuries are from natural causes, self-inflicted by other persons, or when the injuries are to stowaways hiding outside the areas normally available to the passengers and crew, or

- the aircraft sustains damage or structural failure which,
  - adversely affects the structural strength, performance or flight characteristics of the aircraft, and
  - would normally require major repair or replacement of the affected component,
  except for engine failure or damage, when the damage is limited to the engine, its cowlings or accessories; or for damage limited to propellers, wing tips, antennas, tyres, brakes, fairings, small dents or puncture holes in the aircraft skin; or

- the aircraft is missing or is completely inaccessible.

Notes

1. For statistical uniformity only, an injury resulting in death within thirty days of the date of the accident is classified as a fatal injury by ICAO

2. An aircraft is considered to be missing when the official search has been terminated and wreckage has not been located.
Change management: Change management is a systematic approach to dealing with change, both from the perspective of an organisation and on the individual level.

Competency: A combination of skills, knowledge and attitudes required to perform a task to the prescribed standard.

Flight data analysis: A process of analysing recorded flight data in order to improve the safety of flight operations.

Error: An action or inaction by an operational person that leads to deviations from organisational or the operational person’s intentions or expectations.

Hazard: Something with the potential for causing harm.

Human Factors: The minimisation of human error and its consequences by optimising the relationships within systems between people, activities and equipment.

Incident: An occurrence, other than an accident, associated with the operation of an aircraft which affects or could affect the safety of operation.

Operations Safety critical personnel: A person performing or responsible for safety-related work, which includes those performing roles that have direct contact with the physical operation of the aircraft or with those that have contact with personnel that operate the aircraft.

Risk: The probability of incurring some stated harm.

Notes

1. A risk is often specified in terms of an event or circumstance and the consequence that may flow from it.

2. Risk is measured in terms of a combination of the consequences of an event, and its likelihood.

Risk Management: The culture, processes and structures that are directed towards realising potential opportunities whilst managing adverse effects.

Safety Management System: A systematic approach to managing safety, including the necessary organizational structures, accountabilities, policies and procedures.

Training: the process of bringing a person to an agreed standard of proficiency by practice and instruction.

Training Needs Analysis: the identification of training needs at employee, departmental, or organisational level, in order for the organisation to perform effectively.
1. Why Integrate human factors into an RPT AOC holders’ safety management system?

1.1 CAO 82.3 and CAO 82.5 requires RPT AOC holders to ensure that Safety Management Systems (SMS) are established in their organisations and that Human Factors (HF) is integrated into their SMS processes. The practical and methodical application of HF within a SMS is essential to ensure compliance and to optimise human performance within their systems.

2. Basic principles for integrating human factors into a SMS

2.1 The integration of human factors into the safety management system provides a managerial and organisational framework to ensure the systematic identification and analysis of relevant human factors issues, and the application of appropriate tools, methods and measures to address such issues.

2.2 Human factors principles have been summarised from international standards, best practice and in consultation with system safety specialists and human factors experts. These principles will help address the people-related challenges in SMS and achieve the benefits from this. The following summarises the principles that are encompassed in the body of this document:

- Adopt a holistic and integrated approach;
- Put the people at the centre of the system;
- Account for human variability;
- Ensure transparency of organisational processes and actions;
- Take account of social and organisational influences;
- Involve staff and respect and value their input;
- Encourage timely, relevant and clear two-way communication; and
- Ensure fairness of treatment (eg, ‘just culture’ concept).

3. Business benefits for integrating human factors into the SMS

3.1 It is recognised that the application of Human Factors into the SMS has the following safety and business benefits:

- Improves overall safety performance in the organisation and reduces the number of incidents;
- Ensures that human performance is optimally managed to improve safety capacity and efficiency;
- Helps to meet legal and regulatory obligations;
• Demonstrates all reasonable steps have been taken to manage safety and control risk from the perspective of Human Performance;
• Reduces direct costs by considering HF issues in the SMS and as part of any significant change management activity;
• Reduces indirect costs (such as staff turnover and stress-related leave);
• Reduces duplication of activities and effort (and streamline changes) resulting in cost reductions;
• Improves staff motivation across the organisation; and
• Improves staff acceptance of change.

4.1 Operationally the integration of Human Factors into the SMS facilitates continuous improvements to safety, including:
• Promoting a duty of care throughout the organisation;
• Increasing understanding and ownership of the safety processes;
• Encouraging continued safety improvement and the development of a ‘learning organisation’;
• Promoting the use of good communications and feedback throughout the organisation;
• Helping to disseminate appropriate lessons learned;
• Establishing, maintaining, and improving the safety culture of the organisation;
• Improving the integration of HF training processes within the training goals of the organisation;
• Clarifying HF NTS competencies expected of the organisation’s members with respect to safety, and providing a documented process to ensure that standards are maintained;
• Providing effective data collection and analysis methods to support the safety process; and
• Supporting the efficient allocation of resources to the safety process.
5. Integrating HR into the SMS

5.1 Integrating human factors is most essential in the elements of the safety management system dealing with:

- risk management;
- management of change;
- design and procurement of systems, equipment and machinery;
- job and task design;
- selection and training of safety critical personnel;
- safety reporting and flight data analysis; and
- incident investigation.

6. Integrating human factors in risk management

6.1 Human factors risk management allows an organisation to determine where it is vulnerable to human performance limitations. The potential for human error and its sources should be identified and managed through the risk management process.

Note: Also refer to the Safety Risk Management section of CAAP SMS-1(0) – Safety Management Systems for Regular Public Transport Operations.

6.2 Safety management system documentation should clearly demonstrate how human factors have been considered in the management of risk.

6.3 Various aspects of human performance should be considered when identifying, assessing and controlling hazards. This includes areas such as prevention, initiation, detection, control, escalation, mitigation, and emergency response.

6.4 Of particular relevance are:

- processes to ensure that the potential for human error is explicitly addressed; and
- the inclusion of human error management, including error recovery actions, within the risk assessment process.

6.5 The risk management process does not change, however, it should include all relevant human factors issues.

6.6 In addition, you should consider:

- all the people who interact with the system;
- reasonably foreseeable non compliance with standard operating procedures;
- paying particular attention to abnormal or infrequent modes of operation; and
- solutions that support the detection, correction and management of errors.
6.7 Typically, control measures for potential and actual human error might focus on human factors aspects such as equipment design, task and job design, workplace design, procedures, training, communication, team work, supervision and monitoring. The most effective controls are either to remove or modify the hazard.

6.8 Human factors should also be considered during the implementation of safety management solutions, and any recommendations should only be considered after taking into account the context of local factors in the working environment, as well as organisational, or systemic factors.

6.9 To ensure the effectiveness of the control measures, a process for monitoring and review should be implemented.

7. Management of change

7.1 The purpose of integrating human factors into the management of change is to minimise potential risks by specifically considering the impact of the change on the people within a system.

7.2 Change has the potential to introduce new, or exacerbate pre-existing, human factors issues. For example, changes in machinery, equipment, technology, procedures, work organisation or work processes are likely to affect performance.

7.3 The magnitude of change, its safety criticality and its potential impact on human performance should be assessed in any change management process.

7.4 Special consideration should be given to the “transition period”. Any human factors issues identified should be clearly documented. In addition the activities utilised to manage these issues should be integrated into the change management plan.

7.5 Some points to consider:

- The change management effort should be commensurate with the operational risk to the organisation;
- Identify all those affected by the change, who have the potential to impact safety;
- Identify how roles and tasks will be affected by the change;
- Identify the risk to human performance associated with the change – including resistance to change;
- Implement risk management strategies to eliminate or mitigate risks associated with the change;
- Assess and monitor any residual risk associated with human performance; and
- Evaluate and review safety performance against stated objectives.
8. Design and procurement

8.1 Design and modification of human-machine interfaces such as display and control systems, alarm systems, signals and warnings, as well as automated systems may involve significant human factors risks.

8.2 Integrating human factors in the early stages of design, modification and procurement is the most effective way of designing out, or managing, human factors risk.

8.3 The design of equipment and machinery can have a major impact on human performance, and steps should be taken to ensure that human-machine interfaces are designed with the user in mind. A human-centred design approach should be taken, and principles of good human-machine interface (HMI) design followed.

8.4 The design of safety-related systems should take into account human capabilities and limitations, both physical and cognitive, and be suitable for the tasks assigned to operators and maintenance staff. A typical approach could include the following:

- The design modification and procurement of systems should consider good human factors practices and principles. For example, International standards for user centred design;
- Design, where possible, systems and equipment to be tolerant of errors made by operators;
- Identification of all the ways that people may potentially interact with the system;
- Assessing any risks associated with those interactions;
- Ensuring risk management strategies are in place to manage the identified risks;
- Assess and monitor any residual risk associated with human interaction; or
- Evaluating and reviewing safety performance against stated objectives.

8.5 Prior to implementing newly designed, modified or procured systems, awareness and/or training of those that interact with the system should be undertaken. All interfaces should follow good human factors practice, and should accommodate the likely level of awareness and/or training of operators (including members of the public where applicable).
9. Job and task design

9.1 Job and task design can contribute to system safety. It refers to the task, equipment, working environment and the user of the system. Improving the design of jobs and tasks, and the workspaces in which they are performed, can significantly improve human performance and reduce the potential for human error.

9.2 Task design is essentially about matching the person and the task – making sure that tasks and activities are appropriate and suited to the human operator’s or team’s capabilities, limitations and personal needs. For example, tasks that involve excessive time pressure, complex sequences of operations, reliance on memory, are physically or mentally fatiguing, etc., are likely to have a negative impact on performance.

9.3 A typical approach may be to:
- identify safety critical tasks, and those who perform them;
- design the task objectives, sequences and actions to be performed;
- structure the task so it supports the safe performance by the individual or team;
- consider the working environment so it supports the safe performance of the task;
- assess the potential risks associated with non compliance, human capabilities and limitations;
- implement risk management strategies to manage identified risks; and
- evaluate safety performance against the stated objectives.

9.4 Example of things you may include are:
- procedures and rules;
- equipment tools and materials;
- human machine interfaces;
- information requirements;
- manning and workload;
- workspace;
- capabilities and skills required;
- team structures;
- communication links;
- rostering;
- rewards and incentives; and
- supervision.
10. Selection and training of safety critical personnel

10.1 It is essential to take proactive steps to integrate human factors into selection, training, and job performance to maximize the ‘task-person fit’ and to reduce the potential for human error.

10.2 It is important to identify and assure the adequacy of training and competency of staff performing critical functions directly affecting safety. A clear demonstration of the adequacy, effectiveness and appropriateness of training and competency should be provided within the safety management system. Particularly, as it relates to human factors principles across the organisation’s SMS.

10.3 Once the competencies for a role (refer to Job and Task Design) have been defined, methods need to be developed for selecting and training people based on these competencies. In some instances people will already be selected, in which case these people should be evaluated against the competencies and training requirements identified in order to “bridge” any discernable gaps.

10.4 A training Needs Analysis (TNA) should be performed. Refer to Section 6 of Human Factors Training and Non-Technical Skills Assessment for RPT Operations CAAP SMS 3(0)

10.5 Develop and implement training, as required.

10.6 Evaluate and review training effectiveness, and safety performance against stated objectives.

11. Safety reporting systems and data analysis

11.1 The main objective of any safety data collection and analysis system is to make events, hazards, safety trends and their contributing factors visible, understandable, and supported by useable data so that effective corrective action can be taken.

11.2 From the human factors perspective, the behaviour of individuals or groups involved in incidents or “near misses” may not differ greatly from that observed when accidents occur. Generally, the cognitive failures, problems in decision making, communication breakdowns, distractions, and all the other factors which contribute to the sum total of behaviour in an accident will also be present in incidents.

11.3 It is important that the reporting system, as identified in the SMS, should incorporate the identification of contributing human factors. In addition, staff should be trained and encouraged to identify and report contributing human factors in hazards or occurrences.
11.4 Systems to encourage open reporting based on trust, acceptance and motivation include:

- non-punitive, confidential hazard and incident reporting systems;
- a clear and accessible process for reporting issues;
- formal and informal meetings to discuss safety concerns; and
- feedback from management about action taken as a result of hazard and incident reports or safety meetings.

*Note:* Also refer to the Safety Risk Management section of SMS CAAP SMS 1(0) - Safety Management Systems for RPT Operations.

11.5 The classification of operator errors and contributing factors in any accident and incident data collection system should be based on a taxonomy that is carefully aligned with the model or framework used for the investigation and hazard reduction components of the safety management system.

12. **Investigation**

12.1 It is essential that when incidents and accidents do occur that the contribution of human factors is properly investigated. This is done so that the organisation can learn from incidents and near misses in order to protect itself against the consequences of failing to accommodate human limitations in the design and operation of aviation systems.

12.2 The human factors component of investigation should be based on a model or framework for systemic investigations considering human error, both at the individual and organisational levels. A number of human error models and frameworks (such as Reason’s model) have been developed over the last two decades to aid in understanding how humans err and how accidents/incidents occur in the larger context of the systems in which these accidents/incidents take place.

12.3 Investigators should be trained in basic human factors concepts, and procedures should be designed to examine the detail of human performance factors that may have contributed to the event. These include the systemic sources of the failure (e.g. component failures, design deficiencies of equipment and/or infrastructure, inadequate procedures, and lack of training).
